The big idea

Distance is a **tunable resolution knob** on musical structure — sweeping $d_1 \rightarrow d_3 \rightarrow d_2$ distills a piece down to its **core cyclic skeleton**.

- **Three path distances:** d_1 (min edges), d_2 (min weight — the only metric), d_3 (hybrid).
- **Proven ordering** $d_2 \leq d_3 \leq d_1$ lifts to a **nontrivial barcode injection** $\text{bcd}_1(d_2) \hookrightarrow \text{bcd}_1(d_3) \hookrightarrow \text{bcd}_1(d_1)$ (Heo–Choi–Jung 2025).
- **Validated** on real Korean court music — an exact match to the paper’s Table 1.

Cycle skeleton extraction

On *Sanghyeondodeuri* (geomungo): as $d_1 \rightarrow d_3 \rightarrow d_2$, the H_1 barcode thins $|\text{bcd}_1| = 7 \rightarrow 4 \rightarrow 3$ — only the robust core loops survive.

From music to a graph

Each **node** = (pitch, duration); an **edge** joins consecutive notes; the **weight** is $1/(\text{co-occurrence count})$ — frequent neighbors are closer. Rests are skipped.

The music network of *Sanghyeondodeuri* (geomungo).

A universal ordering

For every pair of nodes,

$$d_2(v, w) \leq d_3(v, w) \leq d_1(v, w).$$

This carries over to one-dimensional persistent homology.

Barcode injection

The birth edges nest, $B_2 \subseteq B_3 \subseteq B_1$, giving injections

$$\text{bcd}_1(d_2) \hookrightarrow \text{bcd}_1(d_3) \hookrightarrow \text{bcd}_1(d_1).$$

A **nontrivial theorem** for path-representable distances (Heo–Choi–Jung 2025, arXiv:2501.03553).

Each cycle keeps its **birth**; its **lifespan** grows $d_2 \leq d_3 \leq d_1$, and the number of cycles can only increase.

On real music: d_1 points lie above d_2 — longer lifespans, shared births.

Why it matters

The same piece yields *different but nested* topological readings. d_2 exposes the robust core; d_1 adds finer, peripheral loops. The changes are **systematic, not random**.

Evidence on real music

Distance matrices: d_2 (cool/smooth) $\rightarrow d_1$ (hot) the ordering is visible.

H_1 barcodes:
 $|\text{bcd}_1(d_1)|, |\text{bcd}_1(d_3)|, |\text{bcd}_1(d_2)| = 7, 4, 3$; lifespans grow, births shared.

Distilling the core

Ranking d_1 cycles by how far down they survive ($\rightarrow d_3 \rightarrow d_2$) gives a principled **importance hierarchy of musical loops** — a multi-resolution descriptor of a piece.

Takeaways & future work

- Distance choice = a tunable lens; results are nested, not arbitrary.
- Toward **AI music composition** with multiple stylistic perspectives from one source.

Interactive explorer & audio demos on the project page.

Only d_2 is a metric

d_2 satisfies the triangle inequality; d_1 and d_3 can violate it (a heavy direct edge). Yet all three give meaningful musical structure.
